DIGITAL ASSESSMENT - 1

Q) Explain the various issues in the design of code generation.

The various issues are

- (i) Input to code generators → It is the intermediate code generated by the front end, along with information in the symbol table that determines the run times address of the data object.
- (ii) Target program → It is the output of the code generator. Absolute machine language as output that it can be fixed in memory location and can be immediately executed. Reallocation machine language as an output allows sub program & subroutine to the compiled separately. Assembly language as output makes the code generation easier.
- (iii) Memory management → Mapping the names in the source program to the addresses of data object is done by the front end and the code generator.
- (iv) Instruction selection → selecting the best instruction will improve the efficiency of program. It includes the instruction that should be complete & uniform & its play major role when efficiency is considered.
- (v) Register allocation → Use of register make the computer faster in the comparison to that memory. → During register allocation we select only those set of variables that will reside in the register. → During a subsequent register assignment, the specific register is picked to variables.
- (vi) Evaluation order → The code generator decide the order in which the instruction will be executed. The order of computation affects the efficiency of the code.

(viii) Approaches to code generation \rightarrow It always generate the code of correct. It is essential because of the number of special case that a code generator might face.

SRUTHI.S
19MID005

Q. Explain code generation phase with simple code generation algorithm.

The following action are $X := Y \text{ op } Z$.

- Invoke a function get reg. to determine the location L, where the result of the computation $Y \text{ op } Z$ should be stored.
- Consult the address descriptor for Y to determine Y' , the current location of Y prefer the register for Y' if the value of Y is currently both in memory & register.
- Generate the instruction $\text{OP } Z', L$ where Z' is a currently location of Z . Prefer a register to a memory location if Z is in both.
- If the current values of Y or Z have no next uses, are not live or exit from the block, and are in registers. After execution of $X := Y \text{ op } Z$, it will no longer contain Y or Z .

CamScanner

Q. → Q. Find recursive descent parser

$$E \rightarrow i E' \\ E' \rightarrow i E' \mid e$$

EC()

```
{
    l = getChar()
    if (l == '(')
    {
        match('(');
        E'();
    }
}
```

b1 C()

```
{
    l = getchar();
    if (l == '+')
    {
        match('+');
        match('i');
        E();
    }
    else
        return;
}
```

match (char t)

```
{
    if (l == k)
        l = getChar(),
    else
        printf("error")
```

y
main()

```
{
    EC();
    if (l == '$')
        printf("parsing success");
```

(1) Discuss the role of finite automata in compiler

→ finite automata is a state machine that takes a string a symbol as input & changes its state accordingly. It is a recognizer for regular expression when a regular expression string is fed into finite automata.

The machine consists

$Q \rightarrow$ set of state $\Sigma \rightarrow$ input symbol $q_0 \rightarrow$ starting state

$F \rightarrow$ final state $\delta \rightarrow$ transition function

state → represented by circles. start state → The state where the automata starts. final state → The state where the automata ends.

transition → It happens from 1 state to another when a desire symbol is found.

Scanned with
CamScanner

Q. #3 State what strategy lex should adopt if keywords are not reserved words. SRUTHI.S
 lex pattern are standard unix regular expression using symbol.

| Standard & regular expression | Matches | Example |
|--------------------------------|--|-----------|
| c | single character not operator | x |
| \c | Any character following | * |
| "s" | s literally | " * " * |
| . | Any single character except () | a.b. |
| ^ | Beginning of line | abc |
| \$ | End of line | abc\$ |
| () | Any character ins | [abc] |
| [AS] | Any except character not s | [!abc] |
| r ⁰ | Zero | a* |
| r ¹ | One | at |
| r [?] | Zero | Q? |
| r{m,n} | m to n occurrence of r | a{1,s} |
| r ₁ r ₂ | r ₁ then r ₂ | ab |
| (r) | r | (a:b) |
| r ₁ /r ₂ | r ₁ when followed by r ₂ | Abc / 123 |
| r ₁ r ₂ | r ₁ or r ₂ | a:b |

Q. #3 Write a short note on input buffer with LA.
 → The lexical analyzers scans the input from left to right one character at a time. It uses two pointers begins ptr (bp) & forward to keep back of the pointer of the

Input scanned. The forward ptr moves ahead to search for end of lexeme. As soon as blank space is encountered, it indicates end of lexeme.

SRUTHI.S

Q1) Discuss the role of finite automata in compiler
 → Finite automata is a state machine that takes a string as input & changes its state accordingly. It is a recognizer for regular expression when a regular expression string is fed into finite automata.

The machine consists

S → set of states ε → input symbol q → starting state

F → final state δ → transition function

State → represented by circles. start state → The state where the automata starts. Final state → The state where the automata ends.

Transition → It happens from 1 state to another when a definite symbol is found.

(Q) ~~say state what strategy lex should adopt if keywords are not reserved words~~ SRUTHI.S
 Lex pattern are standard unix regular expression using symbol.

| Standard regular expression | Matches | Example |
|--------------------------------|--|-----------|
| c | single character, not operator | x |
| \c | Any character following | * |
| "s" | string s literally | "**" |
| . | Any single character except () | a.b. |
| ^ | Beginning of line | abc |
| \$ | End of line | abc\$ |
| () | Any character ins | [abs] |
| [AS] | Any character except character not s | [abc] |
| r* | zero | a* |
| r+ | one | a+ |
| r? | zero | a? |
| r{m,n} | m to n occurrence of r | a{1,s} |
| r ₁ r ₂ | r ₁ then r ₂ | ab |
| (r) | r | (a:b) |
| r ₁ /r ₂ | r ₁ when followed by r ₂ | Abc / 123 |
| n r ₂ | n or r ₂ | a: b |

37) \Rightarrow Define activation tree:

\rightarrow Whenever a procedure is executed its activation record is stored on the stack, also known as control stack when a called procedure is executed, it returns the control back to the caller.

\rightarrow This type of control flow makes it easier to represent a series of activation in the form of a tree known as Activation tree.

Q7) \Rightarrow 2. Explain input buffering technique:

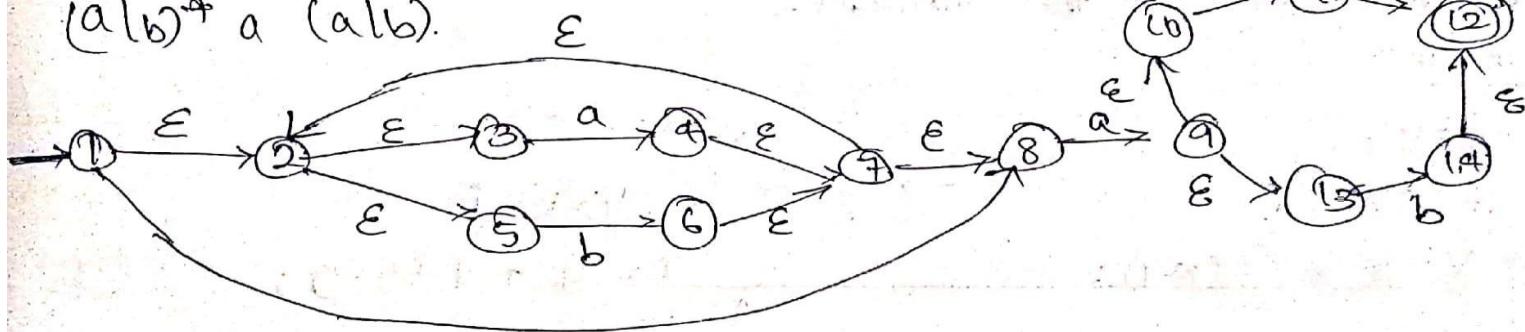

\rightarrow To ensure that a right lexeme is found, one (or) more character have to be looked up beyond the next lexeme. Hence a buffer scheme is introduced to handle large look heads safely.

Three approaches:

- * By using a lexical generator: In this generator provide routine for reading & buffering input.
- * By writing the lexical analysis in a conventional system programming language using I/O facilities of that language to read the input.
- * By assembly language & explicit managing reading of input.

Q7) \Rightarrow 3. Construct NFA from $(ab)^* a (ab)$ using Thompson construction algorithm.

$(ab)^* a (ab)$.

Q7) \Rightarrow 4. Find ϵ FIRST & FOLLOW:

$S \Rightarrow PQR$ | $Q \Rightarrow c \mid d \mid \epsilon$
 $P \Rightarrow a \mid Rb \mid \epsilon$ | $R \Rightarrow e \mid f$

| States | FIRST | FOLLOW |
|--------|----------------------------------|------------------|
| S | {a, ϵ , c, d, f} | {\$, b} |
| P | {a, ϵ , f, ϵ } | {c, d, e, f, \$} |
| Q | {c, d, ϵ } | {e, f, \$} |
| R | { ϵ , f} | {b, \$} |

④ Explain & example following code optimization
at common sub expression elimination :-

Idea → replace an expression with previously stored evaluation of that expression.

SRUTI'S
19M100053

Example:-

$$[a + i * 4] = [a + i * 4] + 7.$$

common subexpression elimination removes the redundant add & multiply.

$$t = a + i + a ; \quad [t] = [t] + 1.$$

Always improves performance.

b) copy propagation:-

Idea → If one variable is assigned to another, replace uses of the assigned variable with the copied variable. Need to know where the copies of the variable.

Example:-

$$x = y ;$$

$$\text{if } (x > y) \{$$

$$x = x + f(x-1) ;$$

}

$$x = y ;$$

$$\text{if } (y > 1) . \{$$

$$x = y + f(y-1) ;$$

}

Can make the first assignment x dead code.

c) dead code elimination:-

Idea → If a side free statement can never be observed, it is safe to eliminate the statement. A variable dead if it is never used after it is defined.

$$x = y + y \quad // x \text{ is dead?}$$

∴ // x never used

$$x = z * z$$

→ ..

$$x = z * z$$

d.4 code motion:

Idea \rightarrow The code motion just means that the code is moved out of the loop as it won't have any difference if it is performed inside the loop repeatedly. The compiler is taking the code that doesn't need to be in the loop & making it outside of it. For the optimization process.

- ④ \Rightarrow 2.4 Eliminating left recursion, left factoring, finding first & follow.

$$E \Rightarrow E + T \mid T$$

$$T \Rightarrow id \mid id \cdot [] \mid id[x]$$

$$x \Rightarrow \epsilon, E \mid E$$

Eliminating
left recursion

$$E \Rightarrow \gamma E'$$

$$E' \Rightarrow +TE' \mid \epsilon$$

$$T \Rightarrow [] \mid [x] \mid \epsilon$$

$$x \Rightarrow \epsilon, E \mid E$$

| HIGHES | FIRST | FOLLOW |
|--------|----------|------------|
| E | {id} | {\$,)} |
| E' | {+, ε} | {+, \$} |
| T | {id} | {+, \$, >} |
| T' | {[, ε]} | {[)} |
| x | {id} | {\$} |

- ⑤ \Rightarrow If define handle & handle pruning?

Handle \rightarrow Handle of a right sentential form γ is $\gamma A \rightarrow \beta$ location of β in γ .

$A \rightarrow \beta$ is a handle of $\alpha \beta \gamma$ at the location immediately after the end of α .

Handle pruning \rightarrow The process of discovering a handle of reducing it to the appropriate left hand side is called handle pruning.

$$S = \gamma_0 \Rightarrow \gamma_1 = \gamma_2 \Rightarrow \dots \Rightarrow \gamma_{n-1} \Rightarrow \gamma_n = w$$

- ⑥ \Rightarrow 2.6 construct LR parsing table:

$$E \Rightarrow ETT$$

Scanned with
CamScanner

$$T \Rightarrow F$$

$$\begin{aligned} F &\Rightarrow (E) \\ F &\Rightarrow id \end{aligned}$$

[id & id + id] using stack implementation.

FIRST & FOLLOW:

SRUTHI's
19M1D0053

| STATE | FIRST | FOLLOW |
|-------|-----------|-----------------|
| E | { C, id } | { +,), \$ } |
| E' | { +, ε } | |
| T | { C, id } | { +,), \$, * } |
| T' | { *, ε } | |
| F | { C, id } | { +,), \$, * } |

Parsing table:

| State | Action | | | | | | Global | | |
|-------|----------------|----------------|----------------|----------------|-----------------|----------------|--------|---|----|
| | id | + | * | C |) | \$ | E | T | F |

| $OE_1 + b \mid T_9$ | \$ | Reduced by $E \rightarrow ETT$ |
| OE_1 | \$ | Accept |

(18) \Rightarrow To give the criteria for achieving machine dependent optimization.

\rightarrow It involves transformation that take into consideration, the properties of the target machine like register & special machine instruction sequence.

The measures are

- * Allocation of adequate number of resources to enhance the execution efficiency of the program.
- * Use of immediate instruction wherever required.
- * Use of intermix instruction.

(18) \Rightarrow To construct uncanonical parsing table.

$$\begin{aligned} S &\rightarrow Cc \\ C &\rightarrow CCId. \end{aligned}$$

Augmented grammar

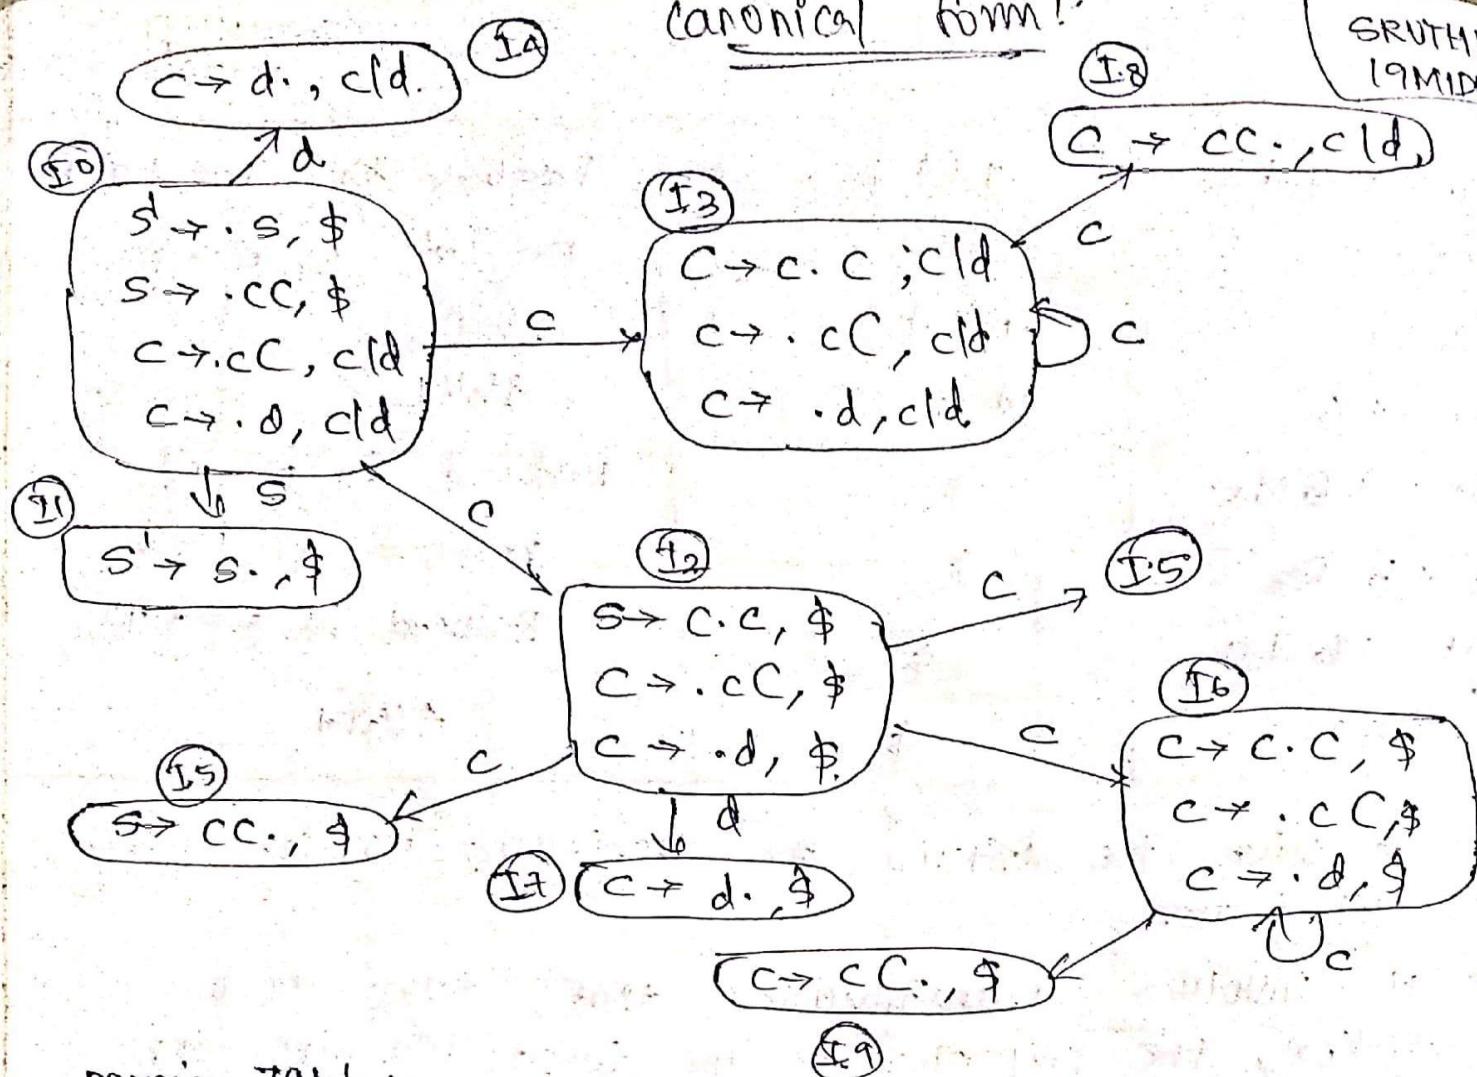

$$S^1 \rightarrow S$$

$$S \rightarrow CC$$

$$C \rightarrow CCId.$$

canonical form!

SRUTHI's

| 9 | | | | R_2 | |

Q7) construct a CFL parsing table

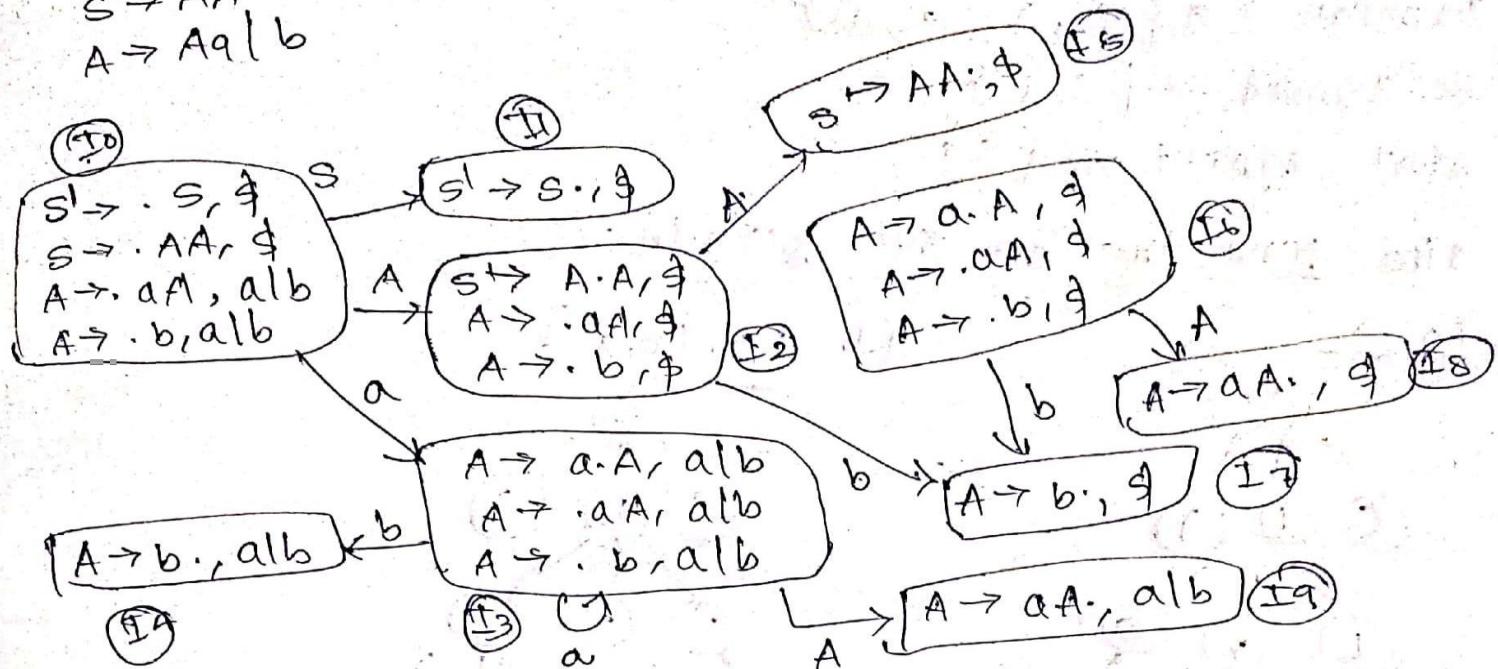

SRUTI11S
19M1D0053

$$S \rightarrow AA \quad | \quad A \rightarrow Aa \quad | \quad b$$

Augmented grammar:

$$\begin{aligned} S' &\rightarrow S \\ S &\rightarrow AA \\ A &\rightarrow Aa \quad | \quad b \end{aligned}$$

Closure ($S' \rightarrow \cdot S, \$$)

look ahead symbol gives where reduction is to be placed

Parsing table:

| States | Action | | | GOTO | |
|--------|--------|-------|---------|------|---|
| | a | b | \$ | S | A |
| 0 | | | | 1 | 2 |
| 1 | | | accept. | | |
| 2 | S_b | S_7 | | | 5 |
| 3 | S_3 | S_4 | | | 9 |
| 4 | r_3 | r_3 | | | 1 |
| 5 | | | | | |
| 6 | S_b | S_7 | | | 8 |
| 7 | | | | | |
| 8 | | | | | |
| 9 | r_2 | | | | |

b. Copy propagation:

Idea \rightarrow If one variable is assigned to another, replace uses of the assigned variable with the copied variable. Need to know where the copies of the variable.

Example:

$x = y ;$

if ($x > y$) {

$x = x + f(x-1) ;$

}

$x = y ;$

if ($y > 1$) {

$x = y + f(y-1) ;$

}

Can make the first assignment x dead code.

c. Dead code elimination:

Idea \rightarrow If a side-free statement can never be observed, it is safe to eliminate the statement. A variable dead if it is never used after it is defined.

$x = y + y$ // x is dead? $\rightarrow \dots$

// x never used

$x = z * z$

$x = z * z$

Dead variables are created by optimization.

d. Code motion:

SRUTHI S
191110053

Idea \rightarrow The code motion just means that the code is moved out of the loop as it won't have any difference if it is performed inside the loop repeatedly. The compiler is taking the code that doesn't need to be in the loop & making it outside of it. for the optimization process.
